# 1 Machine Learning Engineer Nanodegree

### 1.1 Model Evaluation & Validation

# 1.2 Project 1: Predicting Boston Housing Prices

Welcome to the first project of the Machine Learning Engineer Nanodegree! In this notebook, some template code has already been written. You will need to implement additional functionality to successfully answer all of the questions for this project. Unless it is requested, do not modify any of the code that has already been included. In this template code, there are four sections which you must complete to successfully produce a prediction with your model. Each section where you will write code is preceded by a **STEP X** header with comments describing what must be done. Please read the instructions carefully!

In addition to implementing code, there will be questions that you must answer that relate to the project and your implementation. Each section where you will answer a question is preceded by a **QUESTION X** header. Be sure that you have carefully read each question and provide thorough answers in the text boxes that begin with "**Answer:**". Your project submission will be evaluated based on your answers to each of the questions.

A description of the dataset can be found here, which is provided by the **UCI Machine Learning Repository**.

# 2 Getting Started

To familiarize yourself with an iPython Notebook, **try double clicking on this cell**. You will notice that the text changes so that all the formatting is removed. This allows you to make edits to the block of text you see here. This block of text (and mostly anything that's not code) is written using Markdown, which is a way to format text using headers, links, italics, and many other options! Whether you're editing a Markdown text block or a code block (like the one below), you can use the keyboard shortcut **Shift + Enter** or **Shift + Return** to execute the code or text block. In this case, it will show the formatted text.

Let's start by setting up some code we will need to get the rest of the project up and running. Use the keyboard shortcut mentioned above on the following code block to execute it. Alternatively, depending on your iPython Notebook program, you can press the **Play** button in the hotbar. You'll know the code block executes successfully if the message "Boston Housing dataset loaded successfully!" is printed.

```
In [2]: # Importing a few necessary libraries
    import numpy as np
    import matplotlib.pyplot as pl
    from sklearn import datasets
    from sklearn.tree import DecisionTreeRegressor
    import sklearn as sklearn
    from sklearn.metrics import mean_squared_error
    from sklearn import cross_validation
    from sklearn import grid_search
    # Make matplotlib show our plots inline (nicely formatted in the notebook)
```

```
%matplotlib inline

# Create our client's feature set for which we will be predicting a selling price
CLIENT_FEATURES = [[11.95, 0.00, 18.100, 0, 0.6590, 5.6090, 90.00, 1.385, 24, 680.0, 20.20, 332

# Load the Boston Housing dataset into the city_data variable
city_data = datasets.load_boston()

# Initialize the housing prices and housing features
housing_prices = city_data.target
housing_features = city_data.data

print "Boston Housing dataset loaded successfully!"
```

Boston Housing dataset loaded successfully!

# 3 Statistical Analysis and Data Exploration

In this first section of the project, you will quickly investigate a few basic statistics about the dataset you are working with. In addition, you'll look at the client's feature set in CLIENT\_FEATURES and see how this particular sample relates to the features of the dataset. Familiarizing yourself with the data through an explorative process is a fundamental practice to help you better understand your results.

## 3.1 Step 1

In the code block below, use the imported numpy library to calculate the requested statistics. You will need to replace each None you find with the appropriate numpy coding for the proper statistic to be printed. Be sure to execute the code block each time to test if your implementation is working successfully. The print statements will show the statistics you calculate!

```
In [3]: # Number of houses in the dataset
    total_houses = housing_prices.shape[0]

# Number of features in the dataset
    total_features = housing_features.shape[1]

# Minimum housing value in the dataset
    minimum_price = housing_prices.min()

# Maximum housing value in the dataset
    maximum_price = housing_prices.max()

# Mean house value of the dataset
    mean_price = housing_prices.mean()

# Median house value of the dataset
    median_price = np.median(housing_prices)

# Standard deviation of housing values of the dataset
    std_dev = np.std(housing_prices)

# Show the calculated statistics
```

```
print "Boston Housing dataset statistics (in $1000's):\n"
       print "Total number of houses:", total_houses
       print "Total number of features:", total_features
       print "Minimum house price:", minimum_price
       print "Maximum house price:", maximum_price
       print "Mean house price: {0:.3f}".format(mean_price)
       print "Median house price:", median_price
       print "Standard deviation of house price: {0:.3f}".format(std_dev)
Boston Housing dataset statistics (in $1000's):
Total number of houses: 506
Total number of features: 13
Minimum house price: 5.0
Maximum house price: 50.0
Mean house price: 22.533
Median house price: 21.2
Standard deviation of house price: 9.188
```

## 3.2 Question 1

As a reminder, you can view a description of the Boston Housing dataset here, where you can find the different features under **Attribute Information**. The MEDV attribute relates to the values stored in our housing\_prices variable, so we do not consider that a feature of the data.

Of the features available for each data point, choose three that you feel are significant and give a brief description for each of what they measure.

Remember, you can double click the text box below to add your answer!

Answer:

```
RM: it counts the average number of rooms per dwelling in this house, which can be seen as a go
DIS: it measures the weighted distance to five Boston employment cneters. i.e. the advantage o
LSTAT: it provides the percentage of lower status of population, which should be a good measure
```

## 3.3 Question 2

Using your client's feature set CLIENT\_FEATURES, which values correspond with the features you've chosen above?

Hint: Run the code block below to see the client's data.

```
In [4]: print CLIENT_FEATURES

[[11.95, 0.0, 18.1, 0, 0.659, 5.609, 90.0, 1.385, 24, 680.0, 20.2, 332.09, 12.13]]

Answer:
   RM: 5.609
   DIS: 1.385
   LSTAT: 12.13
```

# 4 Evaluating Model Performance

In this second section of the project, you will begin to develop the tools necessary for a model to make a prediction. Being able to accurately evaluate each model's performance through the use of these tools helps to greatly reinforce the confidence in your predictions.

## 4.1 Step 2

In the code block below, you will need to implement code so that the <code>shuffle\_split\_data</code> function does the following: - Randomly shuffle the input data <code>X</code> and target labels (housing values) <code>y. - Split</code> the data into training and testing subsets, holding 30% of the data for testing.

If you use any functions not already accessible from the imported libraries above, remember to include your import statement below as well!

Ensure that you have executed the code block once you are done. You'll know if the shuffle\_split\_data function is working if the statement "Successfully shuffled and split the data!" is printed.

Successfully shuffled and split the data!

### 4.2 Question 4

Why do we split the data into training and testing subsets for our model?

#### ${f Answer:}$

Because we can evaluate the model by doing this. If we build the model on the comprehensive dataset, we will never know how it works facing with unseen data, which is our ultimate goal. Without validating on the test set, the model can be overfit and perform poorly in predicting with new data points.

## 4.3 Step 3

In the code block below, you will need to implement code so that the performance\_metric function does the following: - Perform a total error calculation between the true values of the y labels y\_true and the predicted values of the y labels y\_predict.

You will need to first choose an appropriate performance metric for this problem. See the sklearn metrics documentation to view a list of available metric functions. **Hint:** Look at the question below to see a list of the metrics that were covered in the supporting course for this project.

Once you have determined which metric you will use, remember to include the necessary import statement as well!

Ensure that you have executed the code block once you are done. You'll know if the performance\_metric function is working if the statement "Successfully performed a metric calculation!" is printed.

Successfully performed a metric calculation!

# 4.4 Question 4

Which performance metric below did you find was most appropriate for predicting housing prices and analyzing the total error. Why? -  $\frac{\text{Accuracy}}{\text{Mean Absolute Error (MAE)}}$  -  $\frac{\text{Precision}}{\text{Precision}}$  -  $\frac{\text{Recall}}{\text{Recall}}$  -  $\frac{\text{F1 Score}}{\text{F1 Score}}$  -  $\frac{\text{Mean Squared Error (MSE)}}{\text{Mean Absolute Error (MAE)}}$ 

**Answer:** I choose the Mean Square Error(MSE) for the following reason:

- 1. Accuracy, precision, recall and F1 Score are appropriate for classification problem, in which the ultimate goal is to predict the right label. And in these problems, the response y is always discrete/categorical variable. In this problem, we are going to predct the price of a house, which is a continuous variable. And our goal is to be as close as possible to the real value instead of finding the exact number. That is, we are facing a regression problem.
- 2. Both MSE and MAE are regression metrics. The only difference is MAE uses 11 loss while MSE uses quadratic loss. I choose MSE because it is an unbiased estimator of the variance.

## 4.5 Step 4 (Final Step)

In the code block below, you will need to implement code so that the fit\_model function does the following:
- Create a scoring function using the same performance metric as in Step 2. See the sklearn make\_scorer documentation. - Build a GridSearchCV object using regressor, parameters, and scoring\_function. See the sklearn documentation on GridSearchCV.

When building the scoring function and GridSearchCV object, be sure that you read the parameters documentation thoroughly. It is not always the case that a default parameter for a function is the appropriate setting for the problem you are working on.

Since you are using sklearn functions, remember to include the necessary import statements below as well!

Ensure that you have executed the code block once you are done. You'll know if the fit\_model function is working if the statement "Successfully fit a model to the data!" is printed.

```
In [10]: # Put any import statements you need for this code block

def fit_model(X, y):
    """ Tunes a decision tree regressor model using GridSearchCV on the input data X
    and target labels y and returns this optimal model. """
```

```
# Create a decision tree regressor object
   regressor = DecisionTreeRegressor()
    # Set up the parameters we wish to tune
   parameters = {'max_depth': (1,2,3,4,5,6,7,8,9,10)}
    # Make an appropriate scoring function
   scoring_function = sklearn.metrics.make_scorer(performance_metric, greater_is_better = Fal
    # Make the GridSearchCV object
   reg = grid_search.GridSearchCV(regressor, parameters, scoring_function)
    # Fit the learner to the data to obtain the optimal model with tuned parameters
   reg.fit(X, y)
    # Return the optimal model
   return reg
# Test fit_model on entire dataset
   reg = fit_model(housing_features, housing_prices)
   print "Successfully fit a model!"
   print "Something went wrong with fitting a model."
```

### 4.6 Question 5

Successfully fit a model!

What is the grid search algorithm and when is it applicable?

#### Answer:

Here I use Exhaustive Grid Search, which considers all candidates from a grid of parameter values.

It is applicable when the parameter space is not large. If we are facing a large parameter space, we may consider other algorithms such as randomized serch.

### 4.7 Question 6

What is cross-validation, and how is it performed on a model? Why would cross-validation be helpful when using grid search?

#### Answer:

cross-validation works as follow. The K-CV first divides the training set in to K subsets; then for each model it has a K-round training:in the ith training, it uses the k-1 subsets except ith subset as training set and validate the model in the ith subset, then get an error. After finishing the K-round training, it has K errors and then averages them as the error metric of this model. By comparing this error metric of each model, it picks the best model with the smallest error and apply the model to the comprehensive dataset to tune the parameters. It is helpful because it can resolve the issue of lacking enough test data.

# 5 Checkpoint!

You have now successfully completed your last code implementation section. Pat yourself on the back! All of your functions written above will be executed in the remaining sections below, and questions will be asked about various results for you to analyze. To prepare the **Analysis** and **Prediction** sections, you will need to intialize the two functions below. Remember, there's no need to implement any more code, so sit

back and execute the code blocks! Some code comments are provided if you find yourself interested in the functionality.

```
In [11]: def learning_curves(X_train, y_train, X_test, y_test):
             """ Calculates the performance of several models with varying sizes of training data.
                 The learning and testing error rates for each model are then plotted. """
             print "Creating learning curve graphs for max_depths of 1, 3, 6, and 10. . ."
             # Create the figure window
             fig = pl.figure(figsize=(10,8))
             # We will vary the training set size so that we have 50 different sizes
             sizes = np.round(np.linspace(1, len(X_train), 50))
             train_err = np.zeros(len(sizes))
             test_err = np.zeros(len(sizes))
             # Create four different models based on max_depth
             for k, depth in enumerate([1,3,6,10]):
                 for i, s in enumerate(sizes):
                     # Setup a decision tree regressor so that it learns a tree with max_depth = depth
                     regressor = DecisionTreeRegressor(max_depth = depth)
                     # Fit the learner to the training data
                     regressor.fit(X_train[:s], y_train[:s])
                     # Find the performance on the training set
                     train_err[i] = performance_metric(y_train[:s], regressor.predict(X_train[:s]))
                     # Find the performance on the testing set
                     test_err[i] = performance_metric(y_test, regressor.predict(X_test))
                 # Subplot the learning curve graph
                 ax = fig.add_subplot(2, 2, k+1)
                 ax.plot(sizes, test_err, lw = 2, label = 'Testing Error')
                 ax.plot(sizes, train_err, lw = 2, label = 'Training Error')
                 ax.legend()
                 ax.set_title('max_depth = %s'%(depth))
                 ax.set_xlabel('Number of Data Points in Training Set')
                 ax.set_ylabel('Total Error')
                 ax.set_xlim([0, len(X_train)])
             # Visual aesthetics
             fig.suptitle('Decision Tree Regressor Learning Performances', fontsize=18, y=1.03)
             fig.tight_layout()
             fig.show()
In [12]: def model_complexity(X_train, y_train, X_test, y_test):
             """ Calculates the performance of the model as model complexity increases.
                 The learning and testing errors rates are then plotted. """
             print "Creating a model complexity graph. . . "
```

```
# We will vary the max_depth of a decision tree model from 1 to 14
max_depth = np.arange(1, 14)
train_err = np.zeros(len(max_depth))
test_err = np.zeros(len(max_depth))
for i, d in enumerate(max_depth):
    # Setup a Decision Tree Regressor so that it learns a tree with depth d
    regressor = DecisionTreeRegressor(max_depth = d)
    # Fit the learner to the training data
    regressor.fit(X_train, y_train)
    # Find the performance on the training set
    train_err[i] = performance_metric(y_train, regressor.predict(X_train))
    # Find the performance on the testing set
    test_err[i] = performance_metric(y_test, regressor.predict(X_test))
# Plot the model complexity graph
pl.figure(figsize=(7, 5))
pl.title('Decision Tree Regressor Complexity Performance')
pl.plot(max_depth, test_err, lw=2, label = 'Testing Error')
pl.plot(max_depth, train_err, lw=2, label = 'Training Error')
pl.legend()
pl.xlabel('Maximum Depth')
pl.ylabel('Total Error')
pl.show()
```

# 6 Analyzing Model Performance

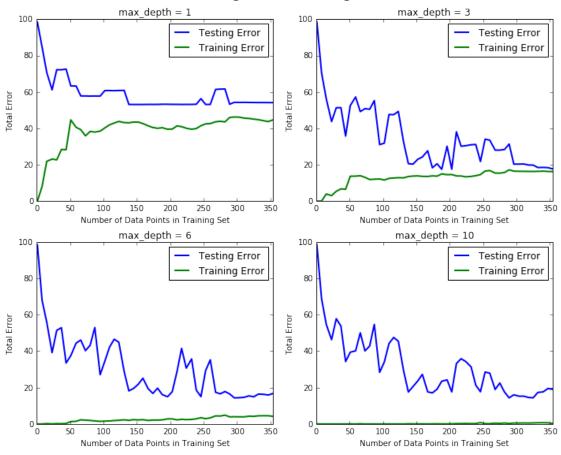

In this third section of the project, you'll take a look at several models' learning and testing error rates on various subsets of training data. Additionally, you'll investigate one particular algorithm with an increasing max\_depth parameter on the full training set to observe how model complexity affects learning and testing errors. Graphing your model's performance based on varying criteria can be beneficial in the analysis process, such as visualizing behavior that may not have been apparent from the results alone.

```
In [13]: learning_curves(X_train, y_train, X_test, y_test)
```

/Users/North\_Point/.graphlab/anaconda/lib/python2.7/site-packages/ipykernel/\_main\_..py:24: DeprecationWa/Users/North\_Point/.graphlab/anaconda/lib/python2.7/site-packages/ipykernel/\_main\_..py:27: DeprecationWa/Users/North\_Point/.graphlab/anaconda/lib/python2.7/site-packages/matplotlib/figure.py:397: UserWarning "matplotlib is currently using a non-GUI backend,"

Creating learning curve graphs for max\_depths of 1, 3, 6, and 10. . .

## 6.1 Question 7

Choose one of the learning curve graphs that are created above. What is the max depth for the chosen model? As the size of the training set increases, what happens to the training error? What happens to the testing error?

**Answer:** I choose the model with  $\max_{depth} = 6$ . We can see from the graph that as the size of training set increases, the training error increases while the testing error decreases.

## 6.2 Question 8

Look at the learning curve graphs for the model with a max depth of 1 and a max depth of 10. When the model is using the full training set, does it suffer from high bias or high variance when the max depth is 1? What about when the max depth is 10?

#### Answer:

Max\_depth = 1: High bias. Because in this graph, the training error and testing error both converge to a high value. That means this model is too weak to explain the pricing – it cannot provide an accurate prediction.

 $Max\_depth = 10$ : High variace. From the graph, even though the training error is constantly low – close to zero, but we can see the testing error is even higher than the model with  $max\_depth = 6$ . That means we have a issue of overfitting, which suggests the possibility of high variance.

In [14]: model\_complexity(X\_train, y\_train, X\_test, y\_test)

Creating a model complexity graph. . .

## 6.3 Question 9

From the model complexity graph above, describe the training and testing errors as the max depth increases. Based on your interpretation of the graph, which max depth results in a model that best generalizes the dataset? Why?

**Answer:** As the max depth increases, the training errors keep decreaseing while the testing errors present the U shape: first decreases then increases

I think max depth = 4 or 5 should results in a model that best generalizes the dataset. Because the testing error reaches the minimum when max\_depth is 4 or 5.

# 7 Model Prediction

In this final section of the project, you will make a prediction on the client's feature set using an optimized model from fit\_model. To answer the following questions, it is recommended that you run the code blocks several times and use the median or mean value of the results.

## 7.1 Question 10

Using grid search on the entire dataset, what is the optimal max\_depth parameter for your model? How does this result compare to your intial intuition?

**Hint:** Run the code block below to see the max depth produced by your optimized model.

```
In [15]: print "Final model optimal parameters:", reg.best_params_
Final model optimal parameters: {'max_depth': 5}
```

**Answer:** The optimal max\_depth for my model is 5, which corresponds with my intuition.

## **7.2** Question 11

With your parameter-tuned model, what is the best selling price for your client's home? How does this selling price compare to the basic statistics you calculated on the dataset?

**Hint:** Run the code block below to have your parameter-tuned model make a prediction on the client's home.

Predicted value of client's home: 20.968

**Answer:** The best selling price for my client's home is 20.968. It is below the mean price but very close to the median.

# 7.3 Question 12 (Final Question):

In a few sentences, discuss whether you would use this model or not to predict the selling price of future clients' homes in the Greater Boston area.

**Answer:** I will not use this model to predict the selling price of future clients' homes in the greater boston area. Because the dataset which is used to train the model includes only the boston area. The pricing of houses in these areas might have different relationship with the listed attributes compared with houses in greater boston area. That could be a issue. In addition, there can also be some other significant attributes that affect house pricing in greater boston area which are not listed in this model.
